

The discovered belief compound passes the false-belief test

On a held-out Sally-Anne scene, the learned fork(derive, commit) abstraction sends the agent to where it believes the goal is; the shortest program in the non-mental fragment sends it to the true goal — the answer three-year-olds give. (24/24 held-out scenes, both.)

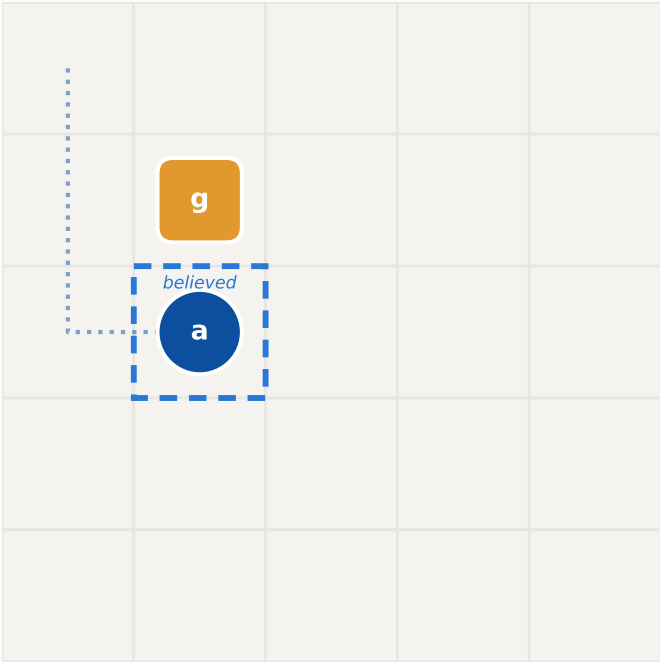

A held-out scene

agent a, true goal g; the goal is "believed" one cell away

Belief compound ✓

learner with the discovered fork(derive, commit)

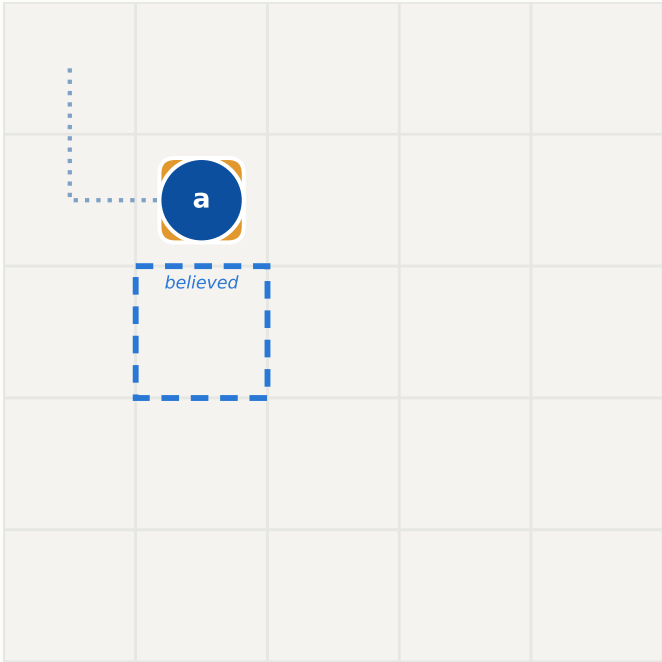

searches the BELIEVED cell — passes

```
(fork (fn_1 1 2 (step 2 down)) (sync_to_world 1))  
20.5 nats
```

Non-mental fragment ✗

learner restricted to physics only

searches the TRUE cell — the naive answer

```
(optimize (neg_dist 2) 1)  
7.9 nats · shortest non-mental
```
